Previously on CS112

Nonregular Languages

- Fine automata proved to be quite powerful for such simple model
- However, they are limited in the sense that there are languages not recognized by any finite automaton
- For example $B = \{0^n 1^n | n \ge 0\}$. Any attempt to find a DFA that recognize B will fail
- The DFA must remember all number of 0 seen so far and the number is not finite and we cannot do that having finite number of states
- ullet We have studied a method for proving that languages such as B are **not regular**

Pumping Lemma for Regular Languages

Theorem

If A is a regular language, then there is a number p (the pumping length) where if s is any string in A of length at least p, then s may be divided into three pieces, s = xyz, satisfying the following conditions:

- 1. for each $i \ge 0$, $xy^iz \in A$
- 2. |y| > 0
- 3. $|xy| \le p$

Pumping Lemma for Regular Languages

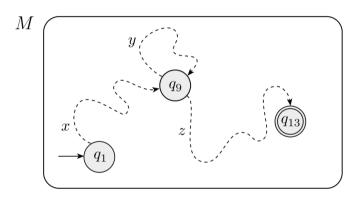

Figure: Example showing how the strings x, y, and z affect M

Section 2

Corresponding to Sipser 2.1

- Until now we introduced two different, though equivalent, methods of describing languages: finite automata and regular expressions
- We showed that many languages can be described in this way but that some simple languages (e.g., $\{0^n1^n|n\geq 1\}$ cannot)
- Now we move to a more powerful method of describing languages: context-free grammars. Such grammars can describe certain features that have a recursive structure, which makes them useful in a variety of applications
- Context-free grammars were first used in the study of human languages. One way of understanding the relationship of terms such as noun, verb, and preposition and their respective phrases leads to a natural recursion because noun phrases may appear inside verb phrases and vice versa. Context-free grammars help us organize and understand these relationships

- An important application of context-free grammars occurs in the specification and compilation of programming languages. A grammar for a programming language often appears as a reference for people trying to learn the language syntax
- Designers of compilers and interpreters for programming languages often start by
 obtaining a grammar for the language. Most compilers and interpreters contain a
 component called a parser that extracts the meaning of a program prior to generating the
 compiled code or performing the interpreted execution
- A number of methodologies facilitate the construction of a parser once a context-free grammar is available. Some tools even automatically generate the parser from the grammar

- The collection of languages associated with context-free grammars are called the
 context-free languages. They include all the regular languages and many additional
 languages. In next lectures, we give a formal definition of context-free grammars and
 study the properties of context-free languages
- We also introduce pushdown automata, a class of machines recognizing the context-free languages. Pushdown automata are useful because they allow us to gain additional insight into the power of context-free grammars

Section 3

Context-free Grammars

Intuition

- A grammar consists of a collection of substitution rules, also called productions
- Each rule appears as a line in the grammar, comprising a symbol and a string separated by an arrow
- The symbol is called a **variable**. The string consists of variables and other symbols called **terminals**
- The variable symbols often are represented by capital letters
- The terminals are analogous to the input alphabet and often are represented by lowercase letters, numbers, or special symbols
- One variable is designated as the start variable
- It usually occurs on the left-hand side of the topmost rule

For example, grammar G_1 contains three rules. G_1 's variables are A and B, where A is the start variable. Its terminals are 0, 1, and #

 $A \rightarrow 0A1$

 $A \rightarrow B$

 $B \to \#$

Intuition

You use a grammar to describe a language by generating each string of that language in the following manner:

- 1. Write down the start variable. It is the variable on the left-hand side of the top rule, unless specified otherwise
- 2. Find a variable that is written down and a rule that starts with that variable. Replace the written down variable with the right-hand side of that rule
- 3. Repeat step 2 until no variables remain

For example, grammar G_1 generates the string 000#111. The sequence of substitutions to obtain a string is called a **derivation**. A derivation of string 000#111 in grammar G_1 is:

$$A \Rightarrow 0A1 \Rightarrow 00A11 \Rightarrow 000A111 \Rightarrow 000B111 \Rightarrow 000#111$$

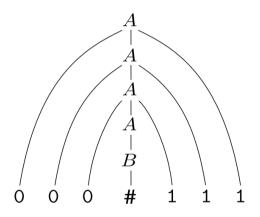

Figure: Parse tree for 000#111 in grammar G_1

Intuition

- All strings generated in this way constitute the language of the grammar
- We write $L(G_1)$ for the language of grammar G_1
- Some experimentation with the grammar G_1 shows us that $L(G_1)=\{0^n\#1^n|n\geq 0\}$
- Any language that can be generated by some context-free grammar is called a context-free language (CFL)
- For convenience when presenting a context-free grammar, we abbreviate several rules with the same left-hand variable, such as $A \to 0A1$ and $A \to B$, into a single line $A \to 0A1|B$

Another example of a context-free grammar, called G_2 , which describes a fragment of the English language:

$$\rightarrow < NOUN - PHRASE> < VERB - PHRASE> < < NOUN - PHRASE> \rightarrow < CMPLX - NOUN>|< CMPLX - NOUN> < PREP - PHRASE> < < VERB - PHRASE> \rightarrow < CMPLX - VERB>|< CMPLX - VERB> < PREP - PHRASE> < < PREP - PHRASE> \rightarrow < PREP> < CMPLX - NOUN> < < CMPLX - NOUN> \rightarrow < ARTICLE> < NOUN> < < CMPLX - VERB> \rightarrow < VERB>|< VERB> < NOUN - PHRASE> < < ARTICLE> \rightarrow a|the < < NOUN> \rightarrow boy|girl|flower < < VERB> \rightarrow touches|likes|sees < < PREP> \rightarrow with$$

Grammar G_2 has

- 10 variables (the capitalized grammatical terms written inside brackets)
- 27 terminals (the standard English alphabet plus a space character)
- 18 rules

Strings from $L(G_2)$ include:

- a boy sees
- the boy sees a flower
- a girl with a flower likes the boy

The derivation for "a boy sees" is:

$$\Rightarrow < NOUN - PHRASE> < VERB - PHRASE>$$
 $\Rightarrow < CMPLX - NOUN> < VERB - PHRASE>$
 $\Rightarrow < ARTICLE> < NOUN> < VERB - PHRASE>$
 $\Rightarrow < ANOUN> < VERB - PHRASE>$
 $\Rightarrow < above box > box > box > cMPLX - VERB>$
 $\Rightarrow < above box > cMPLX - VERB>$

Formal definition

Definition

A context-free grammar is a 4-tuple (V, Σ, R, S) where:

- V is a finite set called the variables
- Σ is a finite set, disjoint from V called the **terminals**
- *R* is a finite set of rules, with each rule being a variable and a string of variables and terminals
- $S \in V$ is the start variable

Formal definition

If u, v, and w are strings of variables and terminals, and $A \to w$ is a rule of the grammar, we say that uAv **yields** uwv, written $uAv \Rightarrow uwv$

We say that u derives v, written $u \stackrel{*}{\Rightarrow} v$, if u = v or if a sequence u_1, u_2, \dots, u_k exists for k > 0 and

$$u \Rightarrow u_1 \Rightarrow u_2 \Rightarrow \cdots \Rightarrow u_k \Rightarrow v$$

The language of the grammar is $\{w \in \Sigma^* | S \stackrel{*}{\Rightarrow} w\}$

In grammar G_1 we have $V = \{A, B\}$, $\Sigma = \{0, 1, \#\}$, S = A and R is the collection of the rules

$$A \rightarrow 0A1$$

$$A \rightarrow B$$

$$B \rightarrow \#$$

In case of grammaer G_2 we have:

$$V = \{ < \textit{SENTENCE} >, < \textit{NOUN} - \textit{PHRASE} >, < \textit{VERB} - \textit{PHRASE} > \\ < \textit{PREP} - \textit{PHRASE} >, < \textit{CMPLX} - \textit{NOUN} >, < \textit{CMPLX} - \textit{VERB} > \\ < \textit{ARTICLE} >, < \textit{NOUN} >, < \textit{VERB} >, < \textit{PREP} > \}$$

and $\Sigma = \{a, b, c, \dots, z\}$ Also we need the blank symbol, placed invisibly after each word

Specification rules

- Often we specify a grammar by writing down only its rules
- We can identify the variables as the symbols that appear on the left-hand side of the rules and the terminals as the remaining symbols
- By convention, the start variable is the variable on the left-hand side of the first rule

Consider grammar $G_3 = (\{S\}, \{a, b\}, R, S)$. The set of rules R is:

$$S
ightarrow aSb|SS|\epsilon$$

- This grammar generates strings such as abab, aaabbb and aababb
- You can see more easily what this language is if you think of a as a left parenthesis "(" and b as a right parenthesis ")"
- Viewed in this way, $L(G_3)$ is the language of all strings of properly nested parentheses
- ullet Observe that the right-hand side of a rule may be the empty string ϵ

$$S \rightarrow (S)|SS|\epsilon$$

Consider grammar $G_4 = (V, \Sigma, R, \langle EXPR \rangle)$. V is $\{\langle EXPR \rangle, \langle TERM \rangle, \langle FACTOR \rangle\}$ and Σ is $\{a, +, x, (,)\}$ The set of rules R is:

$$<$$
EXPR $> \rightarrow <$ EXPR $> + <$ TERM $> | <$ TERM $> <$ TERM $> \rightarrow <$ TERM $> \times <$ FACTOR $> | <$ FACTOR $> <$ FACTOR $> \rightarrow (<$ EXPR $>) | $a$$

The two strings a + axa and (a + a)xa can be generated with grammar G_4

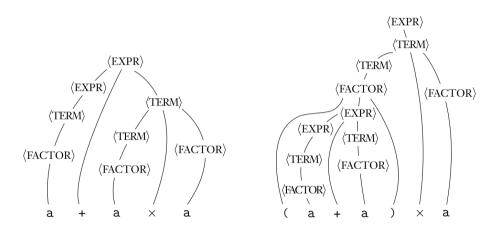

Figure: Parse trees for the strings a + axa and (a + a)xa

- Grammar G_4 describes a fragment of a programming language concerned with arithmetic expressions
- Observe how the parse trees "group" the operations. The tree for a + axa groups the x operator and its operands (the second two a's) as one operand of the + operator
- In the tree for (a + a)xa, the grouping is reversed. These groupings fit the standard precedence of multiplication before addition and the use of parentheses to override the standard precedence
- Grammar G_4 is designed to capture these precedence relations

Section 4

Designing Context-free grammars

The design of context-free grammars requires creativity

Context-free grammars are even trickier to construct than finite automata because we are more accustomed to programming a machine for specific tasks than we are to describing languages with grammars

The following techniques are helpful, singly or in combination, when you're faced with the problem of constructing a CFG

- Many CFLs are the union of simpler CFLs. If you must construct a CFG for a CFL that
 you can break into simpler pieces, do so and then construct individual grammars for each
 piece
- Solving several simpler problems is often easier than solving one complicated problem
- These individual grammars can be easily merged into a grammar for the original language by combining their rules and then adding the new rule $S \to S_1 | S_2 | \dots | S_k$

To get a grammar for the language $\{0^n1^n|n\geq 0\}\cup\{1^n0^n|n\geq 0\}$

$$S
ightarrow 0 S_1 1 | \epsilon$$

for the language $\{0^n1^n|n\geq 0\}$ and the grammar

$$S
ightarrow 1S_10 | \epsilon$$

for the language $\{1^n0^n|n\geq 0\}$. Next we add the rule $S\to S_1|S_2$ and we get the grammar:

$$S
ightarrow S_1 | S_2$$

 $S_1
ightarrow 0 S_1 1 | \epsilon$
 $S_2
ightarrow 1 S_2 0 | \epsilon$

Constructing a *CFG* for a language that happens to be regular is easy if you can first construct a *DFA* for that language. You can convert any *DFA* into an equivalent *CFG* as follows:

- Make a variable R_i for each state q_i of the *DFA*. Add the rule $R_i \to aR_j$ to the *CFG* if $\delta(q_i, a) = q_j$ is a transition in the *DFA*
- Add the rule $R_i \to \epsilon$ if q_i is an accept state of the *DFA*
- Make R_0 the start variable of the grammar, where q_0 is the start state of the machine
- Verify on your own that the resulting CFG generates the same language that the DFA recognizes

Certain context-free languages contain strings with two substrings that are "linked" in the sense that a machine for such a language would need to remember an unbounded amount of information about one of the substrings to verify that it corresponds properly to the other substring as in $\{0^n1^n|n\geq 0\}$

You can construct a *CFG* to handle this situation by using a rule of the form $R \to uRv$, which generates strings wherein the portion containing the u's corresponds to the portion containing the v's.

In more complex languages, the strings may contain certain structures that appear recursively as part of other (or the same) structures.

That situation occurs in the grammar that generates arithmetic expressions Any time the symbol a appears, an entire parenthesized expression might appear recursively instead.

To achieve this effect, place the variable symbol generating the structure in the location of the rules corresponding to where that structure may recursively appear.

Section 5

Ambiguity

- Sometimes a grammar can generate the same string in several different ways
- Such a string will have several different parse trees and thus several different meanings
- This result may be undesirable for certain applications, such as programming languages, where a program should have a unique interpretation

- If a grammar generates the same string in several different ways, we say that the string is derived *ambiguously* in that grammar
- If a grammar generates some string ambiguously, we say that the grammar is ambiguous
- If we consider grammar G_5

$$<$$
 EXPR $> \rightarrow <$ EXPR $> + <$ EXPR $> | <$ EXPR $> x <$ EXPR $> | (<$ EXPR $>)| a$

we observe that it generates the string $a + a \times a$ ambiguously

Grammar G_5 doesn't capture the usual precedence relations and so may group the + before the \times or vice versa.

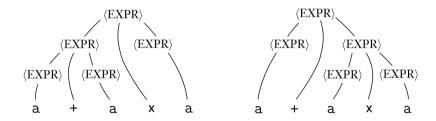

Figure: The two parse trees for the string a+a imes a in grammar G_5

- Grammar G_2 (see previous slides) is another example of an ambiguous grammar
- The sentence the girl touches the boy with the flower has two different derivations
- Give the two parse trees and observe their correspondence with the two different ways to read that sentence (← get a CS112 T-Shirt)

Now we formalize the notion of ambiguity

- When we say that a grammar generates a string ambiguously, we mean that the string has two different parse trees, not two different derivations
- Two derivations may differ merely in the order in which they replace variables yet not in their overall structure
- A derivation of a string w in a grammar G is a **leftmost derivation** if at every step the leftmost remaining variable is the one replaced

Definition

A string w is derived **ambiguously** in context-free grammar G if it has two or more different leftmost derivations. Grammar G is **ambiguous** if it generates some string ambiguously

- Sometimes when we have an ambiguous grammar we can find an unambiguous grammar that generates the same language
- Some context-free languages, however, can be generated only by ambiguous grammars. Such languages are called **inherently ambiguous**
- Study why $\{a^ib^jc^k|i=j\ or\ j=k\}$ is inherently ambiguous (\Leftarrow and get a CS112 T-Shirt)
